Abstract

We investigate the power-suppressed corrections to structure functions in flavour singlet deep inelastic lepton scattering, to complement the previous results for the non-singlet contribution. Our method is a dispersive approach based on an analysis of Feynman graphs containing massive gluons; and our results agree with those obtained from leading infrared renormalon contributions. As in non-singlet deep inelastic scattering we find that the leading corrections are proportional to $1/Q^2$. We find that the singlet contribution becomes important at small x .

1 Introduction

The study of structure functions in deep inelastic lepton scattering (DIS) has received a great impetus from the increasing quantity and kinematic range of the HERA data [1]. Although these functions cannot be calculated using perturbative QCD, their asymptotic scaling violations (logarithmic Q^2 dependence) can be predicted and used to measure the strong coupling α_s . (The same is true of the study of final-state properties, such as fragmentation functions and event shape variables.)

One problem with the measurement of α_s using scaling violation, in either structure or fragmentation functions, is that there is Q^2 dependence associated with power-suppressed (higher-twist) contributions, in addition to the dominant logarithmic dependence. These contributions need to be estimated in order to make use of the wide Q^2 coverage of HERA.

Recently so-called ‘renormalon’ or ‘dispersive’ methods of estimating power-suppressed terms have been applied to a wide variety of observables. By looking at the behaviour of the QCD perturbation series in high orders, one can identify unsummable, factorially divergent sets of contributions (infrared renormalons [2, 3, 4]) which indicate that non-perturbative power-suppressed corrections must be included. The Q^2 -dependence of the leading correction to a given quantity can be inferred, and by making further universality assumptions one may also estimate its magnitude. Tests of these ideas provide information on the transition from the perturbative to the non-perturbative regime in QCD. In particular, one can investigate the possibility that an approximately universal low-energy form of the strong coupling may be a useful phenomenological concept [5, 6, 7].

Such an approach has been applied with some success to e^+e^- fragmentation functions [8] and event shape variables [9, 10, 11], and to flavour non-singlet DIS structure functions [5, 12, 13], fragmentation functions [14] and event shape variables [15]. Note that special care has to be taken when considering non-inclusive observables such as fragmentation functions and event shape variables [16]. There are also renormalon model results for photon-photon scattering [17] and structure functions in flavour singlet DIS [18].

In the present paper we perform the singlet structure function calculation using the dispersive method. We find agreement with the renormalon model result: as in non-singlet DIS, the predicted leading power corrections to these quantities are proportional to $1/Q^2$, but their functional forms are different. In particular there are contributions proportional to $(\log Q^2)/Q^2$, which are not found in the non-singlet case. The hypothesis that they are related to a universal low-energy strong coupling implies that their magnitudes are given by a universal non-perturbative parameters.

In the following section we review the approach of reference [5]. Section 3 presents the standard leading-order perturbative treatment of DIS structure functions. In section 4 we estimate the power-suppressed corrections using the method outlined in section 2. Our results are summarized briefly in section 5.

2 The Dispersive Approach to Power Corrections

We assume that the QCD running coupling $\alpha_s(k^2)$ can be defined for all positive k^2 , and that apart from a branch cut along the negative real axis there are no singularities in the

complex plane. It follows that we may write the dispersion relation:

$$\alpha_s(k^2) = - \int_0^\infty \frac{d\mu^2}{\mu^2 + k^2} \rho_s(\mu^2) , \quad (2.1)$$

where the ‘spectral function’ ρ_s represents the discontinuity across the cut:

$$\rho_s(\mu^2) = \frac{1}{2\pi i} \left\{ \alpha_s(\mu^2 e^{i\pi}) - \alpha_s(\mu^2 e^{-i\pi}) \right\} = \frac{1}{2\pi i} \text{Disc } \alpha_s(-\mu^2) . \quad (2.2)$$

We now consider the calculation of some observable F in an improved one-loop approximation which takes into account one-gluon contributions plus those higher-order terms that lead to the running of α_s . As discussed in [5], we expect, for squared Feynman diagrams containing a single gluon, that

$$F = \alpha_s(0) \mathcal{F}(0) + \int_0^\infty \frac{d\mu^2}{\mu^2} \rho_s(\mu^2) \mathcal{F}(\mu^2/Q^2) , \quad (2.3)$$

where the *characteristic function* $\mathcal{F}(\mu^2/Q^2)$ is obtained by one-loop evaluation of F (divided by α_s) with the gluon mass set equal to μ [3, 9]. The first term on the right-hand side represents the contributions in which a single gluon is produced or exchanged, while the second represents those with more complex final or virtual states (e.g. the ‘decay products’ of a virtual gluon, which contribute to the running of α_s).

We can eliminate $\alpha_s(0)$ by means of the dispersion relation (2.1):

$$F = \int_0^\infty \frac{d\mu^2}{\mu^2} \rho_s(\mu^2) \left[\mathcal{F}(\mu^2/Q^2) - \mathcal{F}(0) \right] . \quad (2.4)$$

By rotating the integration contour separately in the two terms of the discontinuity, we obtain the following contribution to the observable F :

$$F = \int_0^\infty \frac{d\mu^2}{\mu^2} \alpha_s(\mu^2) \mathcal{G}(\mu^2/Q^2) + I_\infty[\alpha_s] , \quad (2.5)$$

where, setting $\mu^2/Q^2 = \epsilon$,

$$\mathcal{G}(\epsilon) = -\frac{1}{2\pi i} \text{Disc } \mathcal{F}(-\epsilon) , \quad (2.6)$$

and the functional I_∞ is some integral around a contour at infinity.

Non-perturbative effects at long distances are expected to give rise to a modification in the strong coupling at low scales, $\delta\alpha_s(\mu^2) = \alpha_s(\mu^2) - \alpha_s^{\text{PT}}(\mu^2)$, $\alpha_s^{\text{PT}}(\mu^2)$ being the perturbatively-calculated running coupling. This generates the following non-perturbative correction to the perturbative prediction:

$$\delta F = \int_0^\infty \frac{d\mu^2}{\mu^2} \delta\alpha_s(\mu^2) \mathcal{G}(\mu^2/Q^2) . \quad (2.7)$$

Since $\delta\alpha_s(\mu^2)$ is limited to low values of μ^2 , there is no contribution to δF from the contour at infinity. Furthermore, the asymptotic behaviour of δF at large Q^2 is controlled by the behaviour of $\mathcal{F}(\epsilon)$ as $\epsilon \rightarrow 0$. We see from (2.6) that no terms analytic at $\epsilon = 0$ can contribute to δF . On the other hand non-analytic terms at small ϵ do contribute, the relevant terms being:

$$\mathcal{F} \sim a_1 \frac{C_F}{2\pi} \sqrt{\epsilon} \quad \implies \quad \delta F = -\frac{a_1}{\pi} \frac{\mathcal{A}_1}{Q} , \quad (2.8)$$

and

$$\mathcal{F} \sim a_2 \frac{C_F}{2\pi} \epsilon \log \epsilon \quad \Longrightarrow \quad \delta F = a_2 \frac{\mathcal{A}_2}{Q^2}, \quad (2.9)$$

where

$$\mathcal{A}_q \equiv \frac{C_F}{2\pi} \int_0^\infty \frac{d\mu^2}{\mu^2} \mu^q \delta\alpha_s(\mu^2). \quad (2.10)$$

Notice that we express the result (2.7) directly in terms of the modification to the strong coupling itself, rather than that in the derived quantity α_{eff} which was used in some previous publications [5, 11, 12],

$$\alpha_{\text{eff}}(\mu^2) = \frac{\sin(\pi\mu^2 d/d\mu^2)}{\pi\mu^2 d/d\mu^2} \alpha_s(\mu^2) = \alpha_s(\mu^2) - \frac{\pi^2}{6} \left(\mu^2 \frac{d}{d\mu^2} \right)^2 \alpha_s(\mu^2) + \dots \quad (2.11)$$

Although α_s and α_{eff} are similar in the perturbative region, they differ substantially at low scales, and the former probably has a simpler behaviour. For example, the even moments of the effective coupling modification,

$$A_{2p} \equiv \frac{C_F}{2\pi} \int_0^\infty \frac{d\mu^2}{\mu^2} \mu^{2p} \delta\alpha_{\text{eff}}(\mu^2), \quad (2.12)$$

have to vanish for all integer values of p , whereas those of $\delta\alpha_s$ do not. The translation dictionary for the moments is in any case rather simple:

$$\mathcal{A}_{2p+1} = (-1)^p (p + \tfrac{1}{2}) \pi A_{2p+1}, \quad \mathcal{A}_{2p} = (-1)^p p A'_{2p}, \quad (2.13)$$

where

$$A'_{2p} \equiv \frac{d}{dp} A_{2p} = \frac{C_F}{2\pi} \int_0^\infty \frac{d\mu^2}{\mu^2} \mu^{2p} \log \mu^2 \delta\alpha_{\text{eff}}(\mu^2). \quad (2.14)$$

Studies of the non-singlet contribution to DIS structure functions suggest that $\mathcal{A}_2 = -A'_2 \simeq 0.2 \text{GeV}^2$ [12].

This is the formulation of the dispersive approach to power behaved corrections used where there is a single gluon propagator. However, the calculation which follows in section 4 involves two gluons, and so the above argument needs to be generalised.

Where a squared Feynman diagram contains two or more gluons, the generalisation of the above requires a separate independent dispersion relation and dispersive variable associated with each gluon. This leads to a characteristic function $\mathcal{F}(\epsilon_1, \dots, \epsilon_n)$ in all of these variables, and, following the above argument, we will require those terms of $\mathcal{F}$ which are non-analytic at 0 in all the arguments. However, in the case where there are two or more internal gluons all constrained to have the same 4-momentum, we can simplify this to require only one dispersive variable for all of them, as discussed below.

Suppose a squared Feynman diagram contains n such gluons whose 4-momenta are all constrained to be equal to k , for some k . (Although only the case $n = 2$ is relevant to phenomenology, its treatment takes no fewer lines than that of the general case.) Then, by defining $\rho = -k^2/Q^2$, we see that the dependence of the characteristic function $\mathcal{F}$ on $\epsilon_1, \dots, \epsilon_n$ is given by

$$\mathcal{F}(\epsilon_1, \dots, \epsilon_n) = \int \frac{d\rho f(\rho)}{(\rho + \epsilon_1) \cdots (\rho + \epsilon_n)}, \quad (2.15)$$

where the integration limits and the function f depend on the particular calculation. This may be expressed in partial fractions in the form

$$\mathcal{F}(\epsilon_1, \dots, \epsilon_n) = \sum_{i=1}^n \left[\prod_{j \neq i} \frac{1}{\epsilon_j - \epsilon_i} \right] \int \frac{d\rho f(\rho)}{\rho + \epsilon_i}, \quad (2.16)$$

which yields the result

$$\mathcal{F}(\epsilon_1, \dots, \epsilon_n) = \sum_{i=1}^n \left[\prod_{j \neq i} \frac{-\epsilon_i}{\epsilon_j - \epsilon_i} \right] \hat{\mathcal{F}}(\epsilon_i), \quad (2.17)$$

where

$$(-\epsilon)^{n-1} \hat{\mathcal{F}}(\epsilon) = \int \frac{d\rho f(\rho)}{\rho + \epsilon}. \quad (2.18)$$

Now the generalisation of the one-gluon result (2.4) to the multiple-gluon case (which can easily be seen from a generalisation of the argument in [5]) is

$$F = (-1)^n \prod_{j=1}^n \left[\int_0^\infty \frac{d\mu_j^2}{\mu_j^2} \rho_s(\mu_j^2) \sum_{i_j=0}^1 (-1)^{i_j} \right] \mathcal{F}(i_1 \mu_1^2 / Q^2, \dots, i_n \mu_n^2 / Q^2). \quad (2.19)$$

Substituting (2.17) into this gives

$$F = (-1)^n \prod_{j=1}^n \left[\int_0^\infty \frac{d\mu_j^2}{\mu_j^2} \rho_s(\mu_j^2) \sum_{i_j=0}^1 (-1)^{i_j} \right] \sum_{k=1}^n \left[\prod_{l \neq k} \frac{-i_k \mu_k^2}{i_l \mu_l^2 - i_k \mu_k^2} \right] \hat{\mathcal{F}}(i_k \mu_k^2 / Q^2). \quad (2.20)$$

Rotating the integration contour over μ_1^2 , as in the single-gluon case, and noting that only terms with $k = 1$ and $i_1 = 1$ contribute, we obtain

$$\begin{aligned} F &= (-1)^{n-1} \int_0^\infty \frac{d\mu_1^2}{\mu_1^2} \alpha_s(\mu_1^2) \left[\prod_{j \neq 1} \int_0^\infty \frac{d\mu_j^2}{\mu_j^2} \rho_s(\mu_j^2) \sum_{i_j=0}^1 (-1)^{i_j} \frac{\mu_1^2}{i_j \mu_j^2 + \mu_1^2} \right] \hat{\mathcal{G}}(\mu_1^2 / Q^2) + I_\infty[\alpha_s] \\ &= (-1)^{n-1} \int_0^\infty \frac{d\mu_1^2}{\mu_1^2} \alpha_s(\mu_1^2) \left[\prod_{j \neq 1} \int_0^\infty \frac{d\mu_j^2}{\mu_j^2 + \mu_1^2} \rho_s(\mu_j^2) \right] \hat{\mathcal{G}}(\mu_1^2 / Q^2) + I_\infty[\alpha_s], \end{aligned} \quad (2.21)$$

where

$$\hat{\mathcal{G}}(\epsilon) = -\frac{1}{2\pi i} \text{Disc} \hat{\mathcal{F}}(-\epsilon), \quad (2.22)$$

and I_∞ is some integral along a contour at infinity.

Using (2.1) $n - 1$ times one finds

$$F = \int_0^\infty \frac{d\mu^2}{\mu^2} [\alpha_s(\mu^2)]^n \hat{\mathcal{G}}(\mu^2 / Q^2) + I_\infty[\alpha_s]. \quad (2.23)$$

As before, we expect to recover non-perturbative contributions to F from the modification in the strong coupling, $\delta\alpha_s$. The behaviour of any power correction is given by the non-analytic parts of $\hat{\mathcal{F}}(\epsilon)$, in precisely the same way as that given by $\mathcal{F}(\epsilon)$ in the single-gluon case, but the coefficient multiplying the correction is different. In the case $n = 2$, we obtain the following non-perturbative contribution to the observable F :

$$\delta F = \int_0^\infty \frac{d\mu^2}{\mu^2} \left(2\alpha_s(\mu^2) \delta\alpha_s(\mu^2) - [\delta\alpha_s(\mu^2)]^2 \right) \hat{\mathcal{G}}(\mu^2 / Q^2) \quad (2.24)$$

We shall see that the relevant non-analytic contributions are

$$\mathcal{F} \sim a_1 \epsilon \log \epsilon \quad \Longrightarrow \quad \delta F = a_1 \frac{D_1}{Q^2}, \quad (2.25)$$

and

$$\mathcal{F} \sim \frac{1}{2} a_2 \epsilon \log^2 \epsilon \quad \Longrightarrow \quad \delta F = a_2 \frac{D_1}{Q^2} \log \frac{D_2}{Q^2}, \quad (2.26)$$

where D_1 and D_2 are defined by:

$$D_1 \equiv \int_0^\infty \frac{d\mu^2}{\mu^2} \mu^2 \left(2\alpha_s(\mu^2) \delta\alpha_s(\mu^2) - [\delta\alpha_s(\mu^2)]^2 \right), \quad (2.27)$$

$$\log D_2 \equiv \frac{1}{D_1} \int_0^\infty \frac{d\mu^2}{\mu^2} \mu^2 \log \mu^2 \left(2\alpha_s(\mu^2) \delta\alpha_s(\mu^2) - [\delta\alpha_s(\mu^2)]^2 \right). \quad (2.28)$$

While we expect the form of $\alpha_s(\mu^2)$, and hence D_1 and D_2 , to be universal, we have as yet no numerical values for them, (unlike for $\mathcal{A}_2$). It will be necessary therefore to extract values for D_1 and D_2 , either from experimental results or from some model of the form of $\alpha_s(\mu^2)$ (of which various models have been proposed [7]).

3 DIS Structure Functions

We consider the deep inelastic scattering of a lepton of momentum l from a nucleon of momentum P , with momentum transfer q . The main kinematic variables are $Q^2 = -q^2$, the Bjorken variable $x = Q^2/2P \cdot q$ and $y = P \cdot q/P \cdot l \simeq Q^2/xs$, s being the total c.m. energy squared.

The differential cross section is

$$\frac{d^2\sigma}{dx dQ^2} = \frac{2\pi\alpha^2}{Q^4} \left\{ [1 + (1-y)^2] F_T(x) + 2(1-y) F_L(x) \right\} \quad (3.1)$$

where $F_T(x) = 2F_1(x)$ and $F_L(x) = F_2(x)/x - 2F_1(x)$ are the transverse and longitudinal structure functions, which also have a weak Q^2 dependence which we do not show explicitly. (For simplicity we are neglecting any contribution from weak interactions, i.e. Z^0 or $W^\pm$ exchange.)

In the parton model, to order α_s^0 , we have

$$F_T(x) = \sum_q e_q^2 [q(x) + \bar{q}(x)], \quad (3.2)$$

$$F_L(x) = 0 \quad (3.3)$$

where $q(x)$ and $\bar{q}(x)$ are the quark and antiquark distributions in the target nucleon.

The $\mathcal{O}(\alpha_s)$ contributions, such as those shown in figure 1, are given by

$$F_i(x) = \frac{\alpha_s}{2\pi} \sum_q e_q^2 \int_x^1 \frac{d\xi}{\xi} \{ C_F C_{i,q}(\xi) [q(x/\xi) + \bar{q}(x/\xi)] + T_R C_{i,g}(\xi) g(x/\xi) \}, \quad (3.4)$$

where $g(x)$ is the gluon distribution, $C_F = 4/3$, $T_R = 1/2$. The coefficient functions $C_{i,j}(\xi)$ are the integrals in the appropriate factorisation scheme, over the final-state variable

$\eta = P \cdot r / P \cdot q$ ($0 \leq \eta \leq 1$), of [19]:

$$C_{T,q}(\xi, \eta) = \frac{\xi^2 + \eta^2}{(1 - \xi)(1 - \eta)} + 2\xi\eta + 2 \quad (3.5)$$

$$C_{L,q}(\xi, \eta) = 4\xi\eta \quad (3.6)$$

$$C_{T,g}(\xi, \eta) = [\xi^2 + (1 - \xi)^2] \frac{\eta^2 + (1 - \eta)^2}{\eta(1 - \eta)} \quad (3.7)$$

$$C_{L,g}(\xi, \eta) = 8\xi(1 - \xi) . \quad (3.8)$$

Here we concentrate on the singlet contribution, i.e. the corrections to $C_{i,g}(\xi)$, as shown in figure 1.

Figure 1: Flavour Singlet Contribution to Deep Inelastic Scattering

4 Power Corrections in Flavour Singlet DIS

In the normal perturbative treatment of DIS, the asymptotic freedom of QCD enables us to treat the initial state partons as free particles confined within the nucleon; and so in a singlet calculation we would start from a free gluon and convolute the perturbative result with the gluon distribution function $g(x)$. We do not know how to do this in a calculation of power corrections, since the models we use consider modifications to the gluon propagator (loop insertions in the renormalon model, or, equivalently, a ‘mass’ in the dispersive approach). Let us therefore perform the calculation by considering our initial state gluon to be radiated from a fermionic parton. We may then try to recover the singlet contribution to the power corrections by deconvoluting the result with the quark to gluon splitting function, as performed in [18], or we may leave the result as it is and interpret it as a second order non-singlet contribution. We might hope that these two interpretations would give similar predictions for power-suppressed corrections.

Figure 2: Diagrams Generating Flavour Singlet Contribution

Consider the contribution to DIS from the diagrams in figure 2. It is convenient to work in the *Breit frame of reference* [19, 20], which is the rest-frame of $2xP + q$. In this frame the momentum transfer q is purely spacelike, and we choose to align it along the $+z$ axis.

The momentum of the initial state parton is $p = xP/\xi$, ($x \leq \xi \leq 1$); and let us introduce the variables $\rho = -s^2/Q^2$, $\eta = P \cdot r / P \cdot q$, $\bar{\eta} = P \cdot k / P \cdot q$, χ the azimuthal angle between r and s , and γ the azimuthal angle between r and k . There is also an overall azimuthal angle ϕ , the dependence on which is trivial.

In the Breit frame the kinematics are given by:

$$P = \frac{1}{2}Q(1/x, 0, 0, -1/x) \quad (4.1)$$

$$p = \frac{1}{2}Q(1/\xi, 0, 0, -1/\xi) \quad (4.2)$$

$$q = \frac{1}{2}Q(0, 0, 0, 2) \quad (4.3)$$

$$s = \frac{1}{2}Q(s_0, s_\perp \cos \chi, s_\perp \sin \chi, s_3) \quad (4.4)$$

$$r = \frac{1}{2}Q(z_0, z_\perp, 0, z_3) \quad (4.5)$$

$$k = \frac{1}{2}Q(\bar{z}_0, \bar{z}_\perp \cos \gamma, \bar{z}_\perp \sin \gamma, \bar{z}_3) . \quad (4.6)$$

The definitions of ρ , η and $\bar{\eta}$ along with the on-shell conditions for the outgoing particles require that

$$s_0 = \frac{1}{\xi} - \rho\xi - \frac{s_\perp^2}{4\rho\xi} \quad s_3 = -\frac{1}{\xi} - \rho\xi + \frac{s_\perp^2}{4\rho\xi} \quad (4.7)$$

$$z_0 = \eta + \frac{z_\perp^2}{4\eta} \quad z_3 = \eta - \frac{z_\perp^2}{4\eta} \quad (4.8)$$

$$\bar{z}_0 = \bar{\eta} + \frac{\bar{z}_\perp^2}{4\bar{\eta}} \quad \bar{z}_3 = \bar{\eta} - \frac{\bar{z}_\perp^2}{4\bar{\eta}} . \quad (4.9)$$

Conservation of the 0th and 3rd components of 4-momentum give the conditions

$$\eta + \bar{\eta} + \rho\xi = 1 \quad (4.10)$$

$$\frac{z_\perp^2}{4\eta} + \frac{\bar{z}_\perp^2}{4\bar{\eta}} + \frac{s_\perp^2}{4\rho\xi} = \frac{1-\xi}{\xi}, \quad (4.11)$$

while conservation of transverse momentum requires that $s_\perp$, $z_\perp$ and $\bar{z}_\perp$ satisfy the triangle inequalities

$$|z_\perp - s_\perp| \leq \bar{z}_\perp \quad (4.12)$$

$$|z_\perp - \bar{z}_\perp| \leq s_\perp. \quad (4.13)$$

Two variables, α and β , are required to parametrise the permitted values of $s_\perp$, $z_\perp$ and $\bar{z}_\perp$. Let us choose to write:

$$z_\perp^2 = \frac{4\alpha\eta(1-\eta)(1-\xi)}{\xi} \quad (4.14)$$

$$\bar{z}_\perp^2 = \frac{4\bar{\eta}(1-\xi)}{(1-\eta)\xi} \left[(1-\alpha)\rho\xi + \alpha\eta\bar{\eta} - 2\cos\beta\sqrt{\alpha(1-\alpha)\eta\bar{\eta}\rho\xi} \right] \quad (4.15)$$

$$s_\perp^2 = \frac{4\rho(1-\xi)}{1-\eta} \left[(1-\alpha)\bar{\eta} + \alpha\eta\rho\xi + 2\cos\beta\sqrt{\alpha(1-\alpha)\eta\bar{\eta}\rho\xi} \right]. \quad (4.16)$$

Given $s_\perp$, $z_\perp$ and $\bar{z}_\perp$, the angles χ and γ are determined up to a sign. We may then choose α , β , η and ρ as the independent variables, with phase space

$$0 \leq \alpha \leq 1, \quad 0 \leq \beta \leq \pi, \quad 0 \leq \eta \leq 1, \quad 0 \leq \rho \leq (1-\eta)/\xi. \quad (4.17)$$

To estimate power corrections to perturbative calculations, we must perform the calculations as though the gluons had small non-zero masses $\mu_1^2 = \epsilon_1 Q^2$ and $\mu_2^2 = \epsilon_2 Q^2$. Using the machinery of section 2 we may write

$$\mathcal{F}_i(x; \epsilon_1, \epsilon_2) = \frac{\epsilon_1 \hat{\mathcal{F}}_i(x; \epsilon_1) - \epsilon_2 \hat{\mathcal{F}}_i(x; \epsilon_2)}{\epsilon_1 - \epsilon_2}, \quad (4.18)$$

where

$$\hat{\mathcal{F}}_i(x; \epsilon) = \frac{\alpha_s^2 T_R C_F}{(2\pi)^2} \sum_q e_q^2 \int_x^1 \frac{d\xi}{\xi} C_i(\xi; \epsilon) q(x/\xi). \quad (4.19)$$

The quantities C_i are the integrated perturbative matrix elements with modified gluon propagators. (Note that these are not the same quantities as those introduced in equation (3.4), since they refer to different diagrams.)

To integrate the matrix elements we apply the operator

$$\int \frac{d^3 \underline{r}}{(2\pi)^3 2r^0} \frac{d^3 \underline{k}}{(2\pi)^3 2k^0} \frac{d^3 \underline{p}'}{(2\pi)^3 2p'^0} (2\pi)^4 \delta^4(p + q - k - r - p'). \quad (4.20)$$

Integrating away $\underline{p}'$ and making substitutions for $\underline{r}$ and $\underline{k}$ gives

$$\frac{Q^2}{32(2\pi)^5} \int \frac{z_\perp dz_\perp d\phi d\eta}{\eta} \frac{\bar{z}_\perp d\bar{z}_\perp d\gamma d\bar{\eta}}{\bar{\eta}} \frac{\delta(A + \sqrt{B + 2z_\perp \bar{z}_\perp \cos \gamma})}{\sqrt{B + 2z_\perp \bar{z}_\perp \cos \gamma}}, \quad (4.21)$$

where A and B do not depend on γ .

Next we integrate over γ . There are two values satisfying the integration condition, and they differ by a sign. This gives

$$\frac{Q^2}{32(2\pi)^5} \int \frac{d\eta}{\eta} \frac{d\bar{\eta}}{\bar{\eta}} \frac{dz_{\perp}^2 d\bar{z}_{\perp}^2}{2z_{\perp}\bar{z}_{\perp}|\sin\gamma|} d\phi. \quad (4.22)$$

Applying the parametrisation in terms of α and β , we find that

$$\frac{\partial(z_{\perp}^2, \bar{z}_{\perp}^2)}{\partial(\alpha, \beta)} = 32(1-\xi)^2 \sin\beta \sqrt{\alpha(1-\alpha)\eta^3\bar{\eta}^3\rho/\xi^3} \quad (4.23)$$

$$2z_{\perp}\bar{z}_{\perp}|\sin\gamma| = 8(1-\xi) \sin\beta \sqrt{\alpha(1-\alpha)\eta\bar{\eta}\rho/\xi}. \quad (4.24)$$

Therefore the integral operator is

$$\frac{Q^2(1-\xi)}{8(2\pi)^5} \int d\rho d\eta d\alpha d\beta d\phi; \quad (4.25)$$

and hence

$$C_i(\xi; \epsilon) = -\frac{1}{\epsilon} \frac{Q^2(1-\xi)}{8(2\pi)^5} \int_0^{1/\xi} d\rho \int_0^{1-\rho\xi} d\eta \int_0^1 d\alpha \int_0^\pi d\beta \int_0^{2\pi} d\phi \frac{f(\xi, \eta, \alpha, \beta, \phi, \rho)}{\rho + \epsilon}, \quad (4.26)$$

where the function f is obtained from the appropriate matrix elements, excluding the denominators of the gluon propagators.

The integration over ϕ is trivial.

The part of this that is nonanalytic as $\epsilon \rightarrow 0$ is the contribution to the integral near $\rho = 0$. Therefore we try to proceed by expressing f as a series expansion in $\rho^{1/2}$ about 0, up to $\mathcal{O}(\rho^2)$. In order to produce valid series expansions, it transpires that we have to divide the η integral into three regions:

- (i) $0 \leq \eta \leq \rho/\kappa$,
- (ii) $\rho/\kappa \leq \eta \leq 1 - \rho\xi - \rho/\kappa$, and
- (iii) $1 - \rho\xi - \rho/\kappa \leq \eta \leq 1 - \rho\xi$,

where κ is some small arbitrary quantity on which the final answer should not depend. (In practice we perform the calculation in the limit of small κ .)

For region (ii) we may directly expand in ρ without any problems. The integral over β is then straightforward, being a sum of terms of the form $\text{const.} \cos^n \beta$, and upon performing this integral the terms in non-integer powers of ρ vanish. The integrals over α , then η , then ρ are not difficult, provided we note that the non-analytic parts of the ρ integrals are given by:

$$\int_0^c \frac{\rho^n}{\rho + \epsilon} d\rho \rightarrow (-1)^{n-1} \epsilon^n \log \epsilon, \quad (4.27)$$

$$\int_0^c \frac{\rho^n \log \rho}{\rho + \epsilon} d\rho \rightarrow \frac{1}{2} (-1)^{n-1} \epsilon^n \log^2 \epsilon. \quad (4.28)$$

Note that because of the limits we have chosen for the η integral, contributions up to $\mathcal{O}(\rho^2)$ will also arise from all higher terms in the series expansion of f . These contributions vanish as $\kappa \rightarrow 0$, so the calculation performed in this limit is valid.

For region (i) such a naive power series becomes invalid, but we may write $\eta = \lambda\rho$ and then expand as before. In contrast to the situation in region (ii) there are now no terms in non-integer powers of ρ . The integration over β may be performed by writing $t = \tan(\beta/2)$, and that over α by making a series of substitutions. The integration over λ (i.e. η) can then be performed, and, since we are only concerned about the limit $\kappa \rightarrow 0$, we neglect all terms that vanish in this limit. The ρ integration then proceeds as above.

For region (iii), we use the symmetry between the outgoing quark and antiquark: if we replace η by $1 - \eta - \rho\xi$ we see that the integrals over regions (i) and (iii) are equal.

Putting all this together we have:

$$\begin{aligned} \xi C_T = & -\frac{2}{9}(2 - 63\xi + 63\xi^2 - 2\xi^3 + 12\log\xi - 27\xi\log\xi - 27\xi^2\log\xi + 12\xi^3\log\xi)\log\epsilon \\ & + \frac{2}{3}(4 + 3\xi - 3\xi^2 - 4\xi^3 + 6\xi\log\xi + 6\xi^2\log\xi)(\log\xi - 1 + \frac{1}{2}\log\epsilon)\log\epsilon \\ & + \frac{2}{5}(2 + 25\xi^2 - 25\xi^3 - 2\xi^5 + 15\xi^2\log\xi + 15\xi^3\log\xi)\epsilon\log\epsilon \\ & - 2(5\xi^2 - 5\xi^3 + 2\xi^2\log\xi + 2\xi^3\log\xi)(\log\xi - 1 + \frac{1}{2}\log\epsilon)\epsilon\log\epsilon, \end{aligned} \quad (4.29)$$

$$\begin{aligned} \xi C_L = & -\frac{8}{3}(1 - 3\xi + 2\xi^3 - 3\xi^2\log\xi)\log\epsilon \\ & - \frac{8}{225}(17 + 75\xi^2 - 125\xi^3 + 33\xi^5 + 30\log\xi + 75\xi^3\log\xi - 45\xi^5\log\xi)\epsilon\log\epsilon \\ & + \frac{8}{15}(2 - 15\xi^2 + 10\xi^3 + 3\xi^5 - 15\xi^3\log\xi)(\log\xi - 1 + \frac{1}{2}\log\epsilon)\epsilon\log\epsilon. \end{aligned} \quad (4.30)$$

The terms that diverge as $\epsilon \rightarrow 0$ are responsible for the logarithmic scaling violations to the structure function (c.f. [5]). To see this, note that the leading divergent pieces (i.e. those proportional to $\frac{1}{2}\log^2\epsilon$ for C_T and to $\log\epsilon$ for C_L) can be expressed as a convolution of the quark to gluon splitting function with the first order gluon coefficient functions:

$$\frac{2(4 + 3\xi - 3\xi^2 - 4\xi^3 + 6\xi\log\xi + 6\xi^2\log\xi)}{3\xi} = 2[\xi^2 + (1 - \xi)^2] \otimes \frac{1 + (1 - \xi)^2}{\xi} \quad (4.31)$$

$$\frac{8(1 - 3\xi + 2\xi^3 - 3\xi^2\log\xi)}{3\xi} = 8\xi(1 - \xi) \otimes \frac{1 + (1 - \xi)^2}{\xi}. \quad (4.32)$$

The subleading divergence in C_T , i.e. that proportional to $\log\epsilon$, is factorisation-scheme-dependent.

The terms proportional to $\epsilon\log\epsilon$ and $\epsilon\log^2\epsilon$ give the $1/Q^2$ power corrections. These are consistent with the results in [18]. Comparison of the results presented here with those in [18] indicate that the terms containing the factor $(\log\xi - 1 + \frac{1}{2}\log\epsilon)$ correspond to the contributions from the double renormalon pole, while those terms without this factor correspond to the contributions from the single renormalon pole. These results also suggest signs for the different contributions: the contributions in [18] from the single poles appear here with a positive sign whereas those from the double poles appear with a negative sign.

This leads to power corrections to the structure functions given by:

$$\delta F_i(x) = \frac{T_R C_F}{(2\pi)^2} \sum_q e_q^2 \int_x^1 \frac{d\xi}{\xi} \delta C_i(\xi) q(x/\xi), \quad (4.33)$$

where

$$\begin{aligned} \delta C_T(\xi) = & \frac{D_1}{Q^2} \left[\frac{2(2 + 25\xi^2 - 25\xi^3 - 2\xi^5 + 15\xi^2\log\xi + 15\xi^3\log\xi)}{5\xi} \right. \\ & \left. - 2(5\xi - 5\xi^2 + 2\xi\log\xi + 2\xi^2\log\xi) \log \frac{D_2\xi}{eQ^2} \right] \end{aligned} \quad (4.34)$$

$$\delta C_L(\xi) = \frac{D_1}{Q^2} \left[-\frac{8(17 + 75\xi^2 - 125\xi^3 + 33\xi^5 + 30 \log \xi + 75\xi^3 \log \xi - 45\xi^5 \log \xi)}{225\xi} + \frac{8(2 - 15\xi^2 + 10\xi^3 + 3\xi^5 - 15\xi^3 \log \xi)}{15\xi} \log \frac{D_2 \xi}{eQ^2} \right]. \quad (4.35)$$

5 Results and Conclusions

The $1/Q^2$ power corrections arising from the diagrams shown in figure 2 are given above in equations (4.34) and (4.35). While we do not know the values of D_1 and D_2 , we can still make some qualitative predictions. Figure 3 shows plots of $K_T(x)$ and $K_L(x)$, defined by

$$\delta F_i(x) = \frac{D_1}{Q^2} \frac{T_R C_F}{(2\pi)^2} K_i(x), \quad (5.1)$$

i.e. $K_i(x)$ are the coefficients of the $1/Q^2$ power correction, excluding the unknown factor D_1 . These were calculated at $Q^2 = 500\text{GeV}^2$, using the corresponding MRST (central gluon) parton distributions [21]. The value of D_2/e was set to be 0.06GeV^2 , i.e. approximately Λ^2 , following the result of [18]. (The qualitative behaviour of the K_i does not change provided we keep $D_2 \ll Q^2$.)

Figure 3: Graph showing $K_T(x)$ and $K_L(x)$.

As can be seen from the graph, $K_T(x)$ and $K_L(x)$ both tend to zero at large x , and both diverge at small x . $K_T(x)$ is positive and $K_L(x)$ is negative, with the magnitude of K_L considerably larger at small x than that of K_T . The corresponding quantity related to F_2/x , which is $K_2/x = K_T + K_L$, also therefore behaves qualitatively like K_L .

Therefore if D_1 is positive, we have a negative correction to both F_2/x and F_L . If D_1 is negative then the correction is positive. In either case the corrections are important at small x .

We do not know the sign or magnitude of D_1 , and there is no a priori reason why it should be either positive or negative. However, since $\mathcal{A}_2$ is positive, we presumably have

$\delta\alpha_s(\mu^2)$ being predominantly positive. We therefore might conjecture that D_1 would also be positive.
